One space: formulation

- Approximate $\mathcal{M}$ by a linear subspace V,

$$\mathsf{dist}(V, \mathcal{M}) \leq \varepsilon, \qquad \mathsf{dim}(V) = n$$

One space: formulation

- Approximate $\mathcal{M}$ by a linear subspace V,

$$\mathrm{dist}(V, \mathcal{M}) \le \varepsilon, \qquad \dim(V) = n$$

- Parameterized-Background Data-Weak (PBDW) [Maday et al., 2015]:

$$A_V(w) := v^* + \eta^*, \quad v^* := \arg\min_{v \in V} \|P_W(u - v)\|, \quad \eta^* := w - P_W v^*$$

One space: formulation

- Approximate $\mathcal{M}$ by a linear subspace V,

$$\text{dist}(V, \mathcal{M}) \leq \varepsilon, \qquad \dim(V) = n$$

- Parameterized-Background Data-Weak (PBDW) [Maday et al., 2015]:

$$A_V(w) := v^* + \eta^*, \quad v^* := \arg\min_{v \in V} \|P_W(u - v)\|, \quad \eta^* := w - P_W v^*$$

- Sharp error bound [Binev et al., 2017]: $\|u - A_V(w)\| \leq \varepsilon \mu(V, W)$

$$\mu(V, W) := \left(\inf_{v \in V} \sup_{w \in W} \frac{\langle v, w \rangle}{\|v\| \|w\|} \right)^{-1}$$

One space: Geometry

Linear MOR

$\text{dist}(V, \mathcal{M}) \leq \varepsilon$

One space: Pros and cons

Pros

- Online efficiency $\mathcal{O}(n^3)$.

- No need to know ε.

- Optimal (worst case sense)
  when $\mathcal{M}$ is a cylinder
  centered in V
  [Binev et al., 2017].

One space: Pros and cons

Pros

- Online efficiency $\mathcal{O}(n^3)$.

- No need to know ε.

- Optimal (worst case sense) when $\mathcal{M}$ is a cylinder centered in V [Binev et al., 2017].

Cons

- Requires $n \leq m$.

- Trade-off between ε and $\mu(V, W)$.

- Limited by the Kolmogorov m-width, $\varepsilon \geq d_m(\mathcal{M})$ where

$$d_n(\mathcal{M}) := \inf_{\substack{X \subset U \\ \dim X = n}} \max_{u \in \mathcal{M}} \mathsf{dist}(X, u).$$

Multi-space approach

Library-based MOR

Multi-space: library-based MOR

- Consider a library of spaces $\mathcal{L}_n^N := \{V_1, \cdots, V_N\}$

$$\mathsf{dist}\Big(\bigcup_{k=1}^N V_k, \mathcal{M} \Big) \leq \varepsilon, \qquad \mathsf{dim}(V_k) \leq n \leq m.$$

Multi-space: library-based MOR

- Consider a library of spaces $\mathcal{L}_n^N := \{V_1, \cdots, V_N\}$

$$\text{dist}\Big(\bigcup_{k=1}^N V_k, \mathcal{M} \Big) \leq \varepsilon, \qquad \dim(V_k) \leq n \leq m.$$

- New benchmark: non-linear Kolmogorov (n, N)-width [Temlyakov, 1998]

$$d_n(\mathcal{M}, N) := \inf_{\#\mathcal{L}_n^N = N} \max_{u \in \mathcal{M}} \min_{V \in \mathcal{L}_n^N} \text{dist}(V, u),$$

which is expected to decay much faster than $d_n(\mathcal{M})$.

Multi-space: library-based MOR

- Consider a library of spaces $\mathcal{L}_n^N := \{V_1, \cdots, V_N\}$

$$\text{dist}\Big(\bigcup_{k=1}^{N} V_k, \mathcal{M} \Big) \leq \varepsilon, \qquad \dim(V_k) \leq n \leq m.$$

- New benchmark: non-linear Kolmogorov (n, N)-width [Temlyakov, 1998]

$$d_n(\mathcal{M}, N) := \inf_{\#\mathcal{L}_n^N = N} \max_{u \in \mathcal{M}} \min_{V \in \mathcal{L}_n^N} \text{dist}(V, u),$$

which is expected to decay much faster than $d_n(\mathcal{M})$.

- Aim for low ε with a low n, thus better stability.

Multi-space: How ?

Each space $V \in \mathcal{L}_n^N$ gives a one-space estimate $A_V(w)$...

Multi-space: How ?

Each space $V \in \mathcal{L}_n^N$ gives a one-space estimate $A_V(w)$...

How to select $V^*(w)$
among this library ?

Multi-space: Selection

Idea [Cohen et al., 2022]: select the "closest" to $\mathcal{M}$

Multi-space: Selection

Idea [Cohen et al., 2022]: select the "closest" to $\mathcal{M}$

- Assume we have $\mathcal{S}$ such that for any $v \in U$,

$$c \text{ dist}(v, \mathcal{M}) \leq \mathcal{S}(v, \mathcal{M}) \leq C \text{ dist}(v, \mathcal{M})$$

Multi-space: Selection

Idea [Cohen et al., 2022]: select the "closest" to $\mathcal{M}$

- Assume we have $\mathcal{S}$ such that for any $v \in U$,

$$c \text{ dist}(v, \mathcal{M}) \leq \mathcal{S}(v, \mathcal{M}) \leq C \text{ dist}(v, \mathcal{M})$$

- Select $V^*(w)$ as

$$V^*(w) \in \underset{V \in \mathcal{L}_n^N}{\text{argmin}} \ \mathcal{S}(A_V(w), \mathcal{M}).$$

Multi-space: Selection

Proposition (Near optimal selection [Cohen et al., 2022])

Assuming that P_W is injective on $\mathcal{M}$ and that $\mu(\mathcal{M}, W) < \infty$,

$$\|u - A_{V^*}(w)\| \le 2\frac{C}{c}\mu(\mathcal{M}, W) \min_{V \in \mathcal{L}_n^N} \|u - A_V(w)\|,$$

$\mu(\mathcal{M}, W)$ reflects how well $\mathcal{M}$ and W are aligned.

Dictionary approach

Dictionary-based MOR

Dictionary approach: Library

- Dictionary of K vectors (or snapshots),

$$\mathcal{D}_K = \{v^{(1)}, \cdots, v^{(K)}\}$$

Dictionary approach: Library

- Dictionary of K vectors (or snapshots),

$$\mathcal{D}_K = \{v^{(1)}, \cdots, v^{(K)}\}$$

- Take as library $\mathcal{L}_m^N = \mathcal{L}_m(\mathcal{D}_K)$, containing all the subspaces spanned by at most m vectors from $\mathcal{D}_K$,

$$\mathcal{L}_m(\mathcal{D}_K) := \Big\{ \sum_{k=1}^{K} x_k v^{(k)} : \ x \in \mathbb{R}^K, \ \|x\|_0 \le m \Big\},$$

Dictionary approach: Library

$\mathcal{L}_m(\mathcal{D}_K)$ is **large** $\longrightarrow$ low ε but not fully explorable.

Dictionary approach: Compressive sensing

Sparse approximation given a
few linear measurements

Dictionary approach: Compressive sensing

Sparse approximation given a few linear measurements $\rightarrow$ Compressive Sensing

Dictionary approach: Compressive sensing

Sparse approximation given a
few linear measurements
$\rightarrow$ Compressive Sensing

- Consider the Basis Pursuit Denoising problem for $\alpha > 0$

$$\mathbf{x}_\alpha(w) := \underset{\mathbf{x} \in \mathbb{R}^K}{\operatorname{argmin}} \frac{1}{2}\|\mathbf{C}\mathbf{x} - \mathbf{w}\|_2^2 + \alpha\|\mathbf{x}\|_1,$$

whose solution is unique and m-sparse under some assumptions.

Dictionary approach: Compressive sensing

Sparse approximation given a
few linear measurements $\rightarrow$ Compressive Sensing

- Consider the Basis Pursuit Denoising problem for $\alpha > 0$

$$\mathbf{x}_\alpha(w) := \operatorname*{argmin}_{\mathbf{x} \in \mathbb{R}^K} \frac{1}{2} \|\mathbf{C}\mathbf{x} - \mathbf{w}\|_2^2 + \alpha \|\mathbf{x}\|_1,$$

whose solution is unique and m-sparse under some assumptions.

- Focus on the space spanned by the support,

$$V_\alpha(w) := \operatorname{span}\{v^{(i)} : \mathbf{x}_\alpha(w)_i \neq 0\} \in \mathcal{L}_m(\mathcal{D}_K)$$

Dictionary approach: Selection

- Use $\mathcal{S}$ to select $V_{\mathcal{S}}(w)$ among the **smaller** library
  $\mathcal{L}(w) := \{V_\alpha(w) : \alpha > 0\}$ and define

$$A_{\mathcal{S}}^{\mathsf{dic}}(w) := A_{V_{\mathcal{S}}(w)}(w)$$

Dictionary approach: Selection

- Use $\mathcal{S}$ to select $V_{\mathcal{S}}(w)$ among the **smaller** library
  $\mathcal{L}(w) := \{V_\alpha(w) : \alpha > 0\}$ and define

$$A_{\mathcal{S}}^{\text{dic}}(w) := A_{V_{\mathcal{S}}(w)}(w)$$

- In practice for efficiency and numerical stability reasons, we only
  compute $\hat{\mathcal{L}}(w) \subset \mathcal{L}(w)$ with $\#\hat{\mathcal{L}}(w) \leq \tau K$.

Dictionary approach: Selection

- Use $\mathcal{S}$ to select $V_{\mathcal{S}}(w)$ among the **smaller** library $\mathcal{L}(w) := \{V_\alpha(w) : \alpha > 0\}$ and define

$$A_{\mathcal{S}}^{\mathsf{dic}}(w) := A_{V_{\mathcal{S}}(w)}(w)$$

- In practice for efficiency and numerical stability reasons, we only compute $\hat{\mathcal{L}}(w) \subset \mathcal{L}(w)$ with $\#\hat{\mathcal{L}}(w) \leq \tau K$.

Proposition (Near optimal selection)

Assuming that P_W is injective on $\mathcal{M}$ and that $\mu(\mathcal{M}, W) < \infty$,

$$\|u - A_{\mathcal{S}}^{dic}(w)\| \leq 2\frac{C}{c}\mu(\mathcal{M}, W) \min_{V \in \hat{\mathcal{L}}(w)} \|u - A_V(w)\|,$$

Parameterized PDEs

Offline-online decomposition for dictionary-based multi-space

Parameterized PDEs: Offline-online decomposition

- Discrete framework $U = \mathbb{R}^{\mathcal{N}}$ with large $\mathcal{N}$.

- **Offline**: Heavy pre-computations independently on w.

- **Online**: Fast computation of $A_{\mathcal{S}}^{\text{dic}}(w)$.

Parameterized PDEs: Framework

- Consider that u solves the operator equation

$$B(\xi)u(\xi) = f(\xi),$$

where the singular values of $B(\xi)$ are **uniformly bounded**,

$$0 < c \leq \min_{v \in U} \frac{\|B(\xi)v\|}{\|v\|} \leq \max_{v \in U} \frac{\|B(\xi)v\|}{\|v\|} \leq C < \infty,$$

Parameterized PDEs: Framework

- Consider that u solves the operator equation

$$B(\xi)u(\xi) = f(\xi),$$

where the singular values of $B(\xi)$ are **uniformly bounded**,

$$0 < c \leq \min_{v \in U} \frac{\|B(\xi)v\|}{\|v\|} \leq \max_{v \in U} \frac{\|B(\xi)v\|}{\|v\|} \leq C < \infty,$$

- Take $\mathcal{S}$ as a **residual norm** as in [Cohen et al., 2022],

$$\mathcal{S}(v, \mathcal{M}) := \min_{\xi \in \mathcal{P}} \|B(\xi)v - f(\xi)\|, \quad \forall v \in U,$$

which satisfies $c \, \text{dist}(v, \mathcal{M}) \leq \mathcal{S}(v, \mathcal{M}) \leq C \, \text{dist}(v, \mathcal{M})$.

Parameterized PDEs: Affine decomposition

* Assume the **affine decompositions**

$$B(\xi) = B_0 + \sum_{q=1}^{d} \theta_q^{(B)}(\xi)B_q \quad \text{and} \quad f(\xi) = f_0 + \sum_{q=1}^{m_f} \theta_q^{(f)}(\xi)f_q,$$

with $B_q : U \longrightarrow U'$ linear operators and $f_q \in U'$.

Parameterized PDEs: Affine decomposition

- Assume the **affine decompositions**

$$B(\xi) = B_0 + \sum_{q=1}^{d} \theta_q^{(B)}(\xi) B_q \quad \text{and} \quad f(\xi) = f_0 + \sum_{q=1}^{m_f} \theta_q^{(f)}(\xi) f_q,$$

with $B_q : U \longrightarrow U'$ linear operators and $f_q \in U'$.

- Then computing $\mathcal{S}$ requires solving the l.s. system

$$\mathcal{S}(v, \mathcal{M}) := \min_{\xi \in \mathcal{P}} \|G(v)\theta(\xi) - g(v)\|, \quad v \in U,$$

where $\theta(\xi) \in \mathbb{R}^{m_B + m_f}$, $G(v) : \mathbb{R}^{m_B + m_f} \longrightarrow U'$ and $g(v) \in U'$.

Parameterized PDEs: Offline-online decomposition

- **Problem**: precomputing the normal equation for $\mathcal{S}$ costs

$$\mathcal{O}\big((m_B K + m_f)^2 \mathcal{N}\big)$$

Parameterized PDEs: Offline-online decomposition

- **Problem**: precomputing the normal equation for $\mathcal{S}$ costs

$$\mathcal{O}\big((m_B K + m_f)^2 \mathcal{N}\big)$$

- **Instead**, we use a random embedding $\Theta \in \mathbb{R}^{k \times \mathcal{N}}$ and consider

$$\mathcal{S}^\Theta(v, \mathcal{M}) := \min_{\xi \in \mathcal{P}} \|\Theta\big(B(\xi)v - f(\xi)\big)\| = \min_{\xi \in \mathcal{P}} \|G^\Theta(v)\theta(\xi) - g^\Theta(v)\|$$

where $G^\Theta(v) \in \mathbb{R}^{k \times (m_B + m_f)}$ and $g^\Theta(v) \in \mathbb{R}^k$.

Parameterized PDEs: Offline-online decomposition

- **Problem**: precomputing the normal equation for $\mathcal{S}$ costs

$$\mathcal{O}\big((m_B K + m_f)^2 \mathcal{N}\big)$$

- **Instead**, we use a random embedding $\Theta \in \mathbb{R}^{k \times \mathcal{N}}$ and consider

$$\mathcal{S}^{\Theta}(v, \mathcal{M}) := \min_{\xi \in \mathcal{P}} \|\Theta\big(B(\xi)v - f(\xi)\big)\| = \min_{\xi \in \mathcal{P}} \|G^{\Theta}(v)\theta(\xi) - g^{\Theta}(v)\|$$

where $G^{\Theta}(v) \in \mathbb{R}^{k \times (m_B + m_f)}$ and $g^{\Theta}(v) \in \mathbb{R}^k$.

Proposition

With $k = \mathcal{O}\Big(\epsilon^{-2}\left(m_B + m_f + \log(\delta^{-1})\right)\Big)$, for any $v \in U$, with probability at least $1 - \delta$ we have

$$\sqrt{1 - \epsilon}\, \mathcal{S}(v, \mathcal{P}) \leq \mathcal{S}^{\Theta}(v, \mathcal{P}) \leq \sqrt{1 + \epsilon}\, \mathcal{S}(v, \mathcal{P}).$$

Parameterized PDEs: Computational aspects

- **Offline cost**: Using a structured embedding Θ (e.g. SRHT),

$$\mathcal{O}\big(\underbrace{mK\mathcal{N}}_{\text{compute } \mathbf{C}} + \underbrace{(m_B K + m_f)\mathcal{N}\log(k)}_{\text{pre-compute } G^\Theta(v) \text{ and } g^\Theta(v)} \big)$$

- **Online cost**: Considering $k = \mathcal{O}(m_B + m_f)$,

$$\mathcal{O}\big(\underbrace{m^2 K}_{\text{LARS}} + \underbrace{k(mm_B + m_f)K}_{\text{prepare l.s.}} + \underbrace{C_{ls}K}_{\text{solve l.s.}} \big)$$

- **Numerical stability** : few affine terms, thus robust to round-off errors.

Parameterized PDEs: Computational aspects

Example when $\theta(\xi) = \xi$ and $f(\xi) = f_0$.

- **Offline cost**:

$$\begin{array}{cc} \text{With random sketching} & \text{With normal equation} \\ \mathcal{O}\big(mK\mathcal{N} + dK\mathcal{N}\log(k)\big) & \mathcal{O}\big(mK\mathcal{N} + d^2K^2\mathcal{N}\big) \end{array}$$

  (with "VS" between the two)

- **Online cost**: Considering $k = \mathcal{O}(d)$,

$$\begin{array}{cc} \text{With random sketching} & \text{With normal equation} \\ \mathcal{O}\big(m^2K + md^2K + d^3K\big) & \mathcal{O}\big(m^2K + m^2d^2K + d^3K\big) \end{array}$$

  (with "VS" between the two)

Numerical Example

Finite Element space $U \subset \mathcal{H}^1_{\Gamma_D}(\Omega)$ endowed with norm $\|\nabla \cdot\|_{\mathcal{L}^2(\Omega)}$

Numerical: Thermal block

$$\mathcal{N} \sim 8\ 000 \quad \text{and} \quad \begin{cases} -\nabla \cdot \big(\kappa \nabla u\big) = 1 & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_D, \\ \kappa = \xi_i & \text{in } \Omega_i,\ 1 \leq i \leq 9, \end{cases}$$

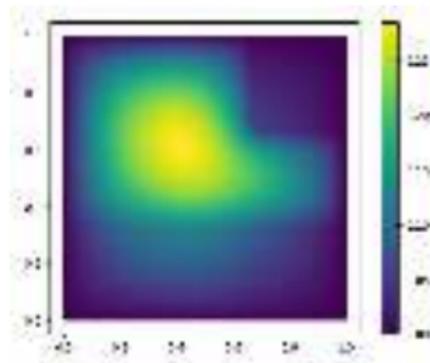

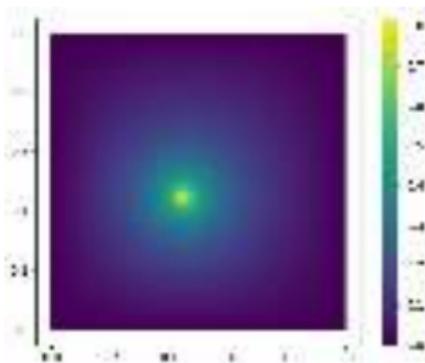

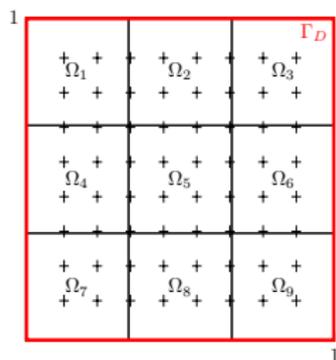

Figure: Left: geometry, with sensors locations (crosses). Middle: Riesz representative of a sensor. Right: a snapshot.
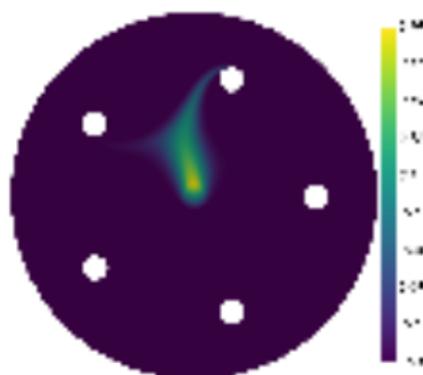

Numerical: Thermal block

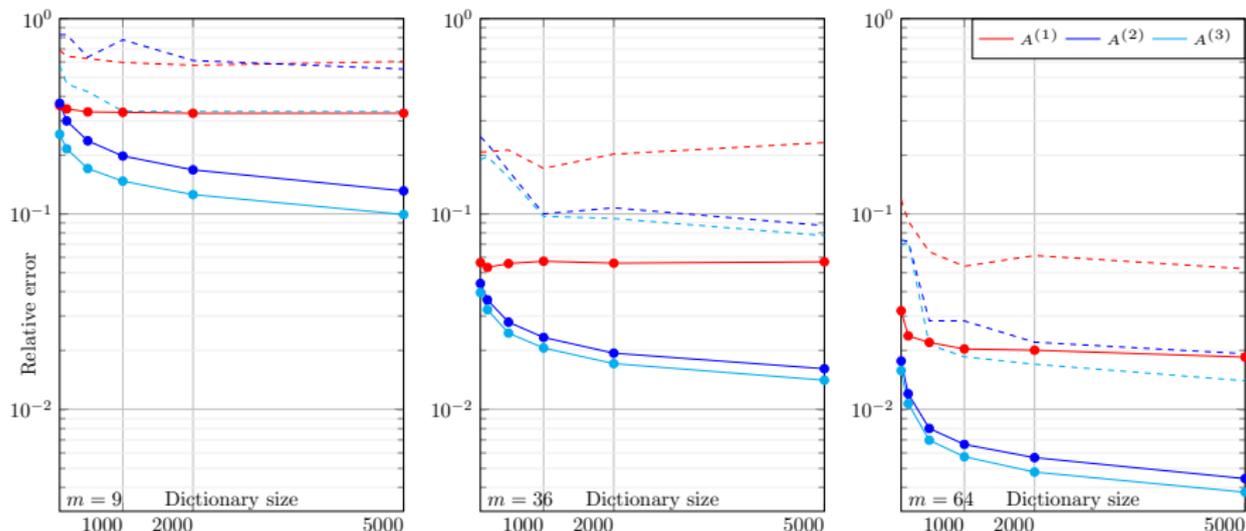

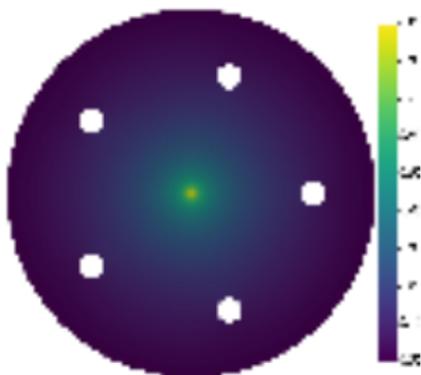

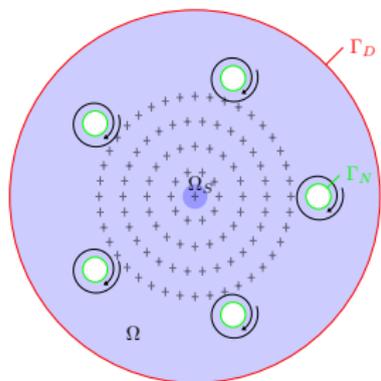

Figure: Evolution of the recovery errors in U-norm, on 500 test snapshots, with growing dictionary sizes K, for $m \in \{9, 36, 64\}$.

Numerical: Advection diffusion

$$\mathcal{N} \sim 150\ 000 \quad \text{and} \quad
\begin{cases}
-0.01\Delta u + \mathcal{V}(\xi) \cdot \nabla u = \dfrac{100}{\pi}\mathbb{1}_{\Omega_S} & \text{in } \Omega, \\
u = 0 & \text{on } \Gamma_D, \\
n \cdot \nabla u = 0 & \text{on } \Gamma_N,
\end{cases}$$

$$\mathcal{V}(\xi) = \sum_{i=1}^{5} \frac{1}{\|x - x^{(i)}\|}\Big(\xi_i e_r(x^{(i)}) + \xi_{i+5} e_\theta(x^{(i)})\Big)$$
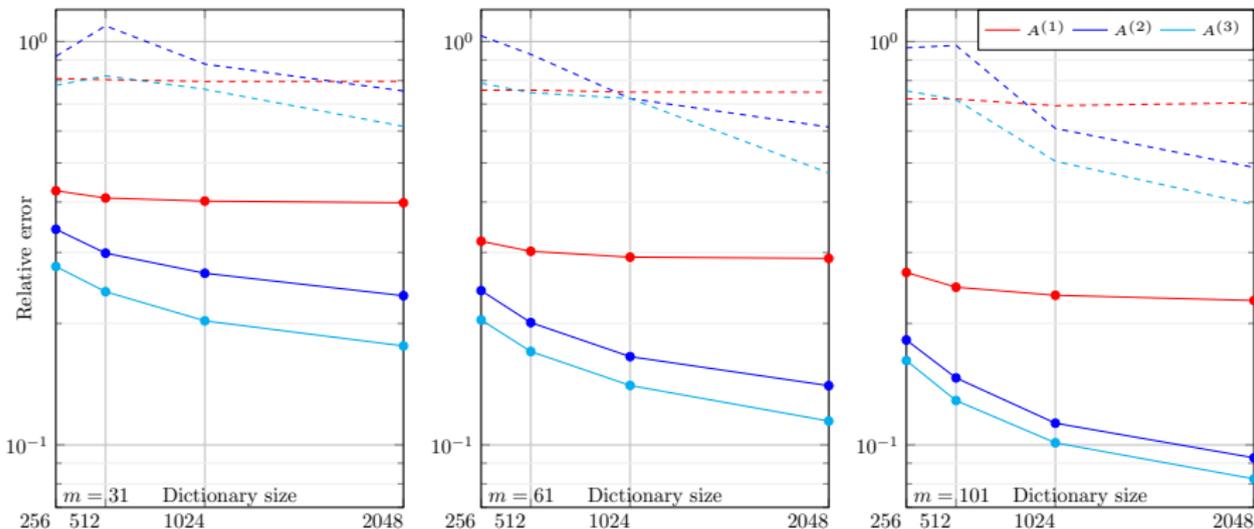

Numerical: Advection diffusion

Figure: Evolution of the recovery errors in U-norm, on 500 test snapshots, with growing dictionary sizes K, for $m \in \{31, 61, 101\}$.

Conclusion

Conclusion

- Dictionary-based multi-space approach for state estimation

- Efficient offline-online decomposition using randomized linear algebra.

- More details in [Nouy and Pasco, 2023] available at
  https://arxiv.org/abs/2303.10771

- Python repo available at
  https://github.com/alexandre-pasco/rla4mor/inverse-problems

Thank you !

Appendix

Appendix: Offline stage

- Write $A_\alpha(w) = \mathbf{U}\mathbf{a}$ with $\mathbf{a} = \mathbf{a}(w) \in \mathbb{R}^{m+K}$ and $\mathbf{U} = (\mathbf{W} \mid \mathbf{V})$.

- Write the l.s. terms to compute $\mathcal{S}^\Theta$ as

$$G^\Theta(A_\alpha(w)) := \left(\Theta B^{(1)} \mathbf{U} \mathbf{a} \mid \cdots \mid \Theta B^{(d)} \mathbf{U} \mathbf{a} \right)$$

$$g^\Theta(A_\alpha(w)) := \Theta f - \Theta B^{(0)} \mathbf{U} \mathbf{a}.$$

- **Offline**: compute $\underbrace{\mathbf{C}}_{\mathcal{O}(mK\mathcal{N})} \in \mathbb{R}^{m \times K}$ and $\underbrace{\Theta B^{(q)} \mathbf{U}}_{\mathcal{O}(K\mathcal{N} \log(\|\|))} \in \mathbb{R}^{k \times (m+K)}$

- Total offline cost (without snapshot computation) is

$$\mathcal{O}\left((d \log(\mathcal{N}) + m) K \mathcal{N} \right) \quad \text{VS} \quad \mathcal{O}\left(d^2 K^2 \mathcal{N} \right)$$

Appendix: Online stage

- **Step 0**: Observe $w = P_w u$.

- **Step 1**: Run LARS to generate $\mathcal{O}(K)$ subspaces, costing $\mathcal{O}(m^2 K)$.

- **Step 2**: Prepare the l.s. systems, each costing $\mathcal{O}(kmd)$.

- **Step 3**: Solve them, each costing $\mathcal{O}(kd^2)$.

- Total online cost with $k = \mathcal{O}(d)$

$$\mathcal{O}(\underbrace{m^2 K}_{\text{LARS}} + \underbrace{md^2 K}_{\text{prepare l.s.}} + \underbrace{d^3 K}_{\text{solve l.s.}}) = \mathcal{O}((m^2 + md^2 + d^3)K).$$
